

Modes of action in ecotoxicology

What can we learn for toxicant detection?

Matthias GROTE, Julie Chevalier
National Hydraulics and
Environment Laboratory – EDF R&D

Content

Introduction – Why should we care about modes of action?

Classification of modes of action:

Narcosis / Baseline Toxicity

Reactivity

Specific modes of action

Joint action of several compounds (mixtures)

Is mixture toxicity predictable?

Are mixture effects relevant in surface waters?

Implications for toxicant detection in toximeter

Introduction

Compounds differ with respect to detectable effects in the toximeter

- ⦿ ratios between alarm thresholds and EC50 values
- ⦿ alarm onset times
- ⦿ response patterns
 - immobilisation
 - excitation

➔ This is not surprising as toxic compounds can interact with the organism in various ways .

The mode of action describes the interaction of the compounds with the organism.

Introduction – Why care for modes of action?

- Understanding why a substance is toxic.
- The mode of action is essential for
 - inter-species extrapolation
 - toxicity prediction from chemical structure
 - Quantitative (Qualitative) Structure Activity Relationship (QSAR)
 - mixture toxicity prediction
 - Concentration Addition (CA) for compounds with similar modes of action
 - Independent Action (IA) for compounds with dissimilar modes of action
 - detectability of compounds in the toximeter?

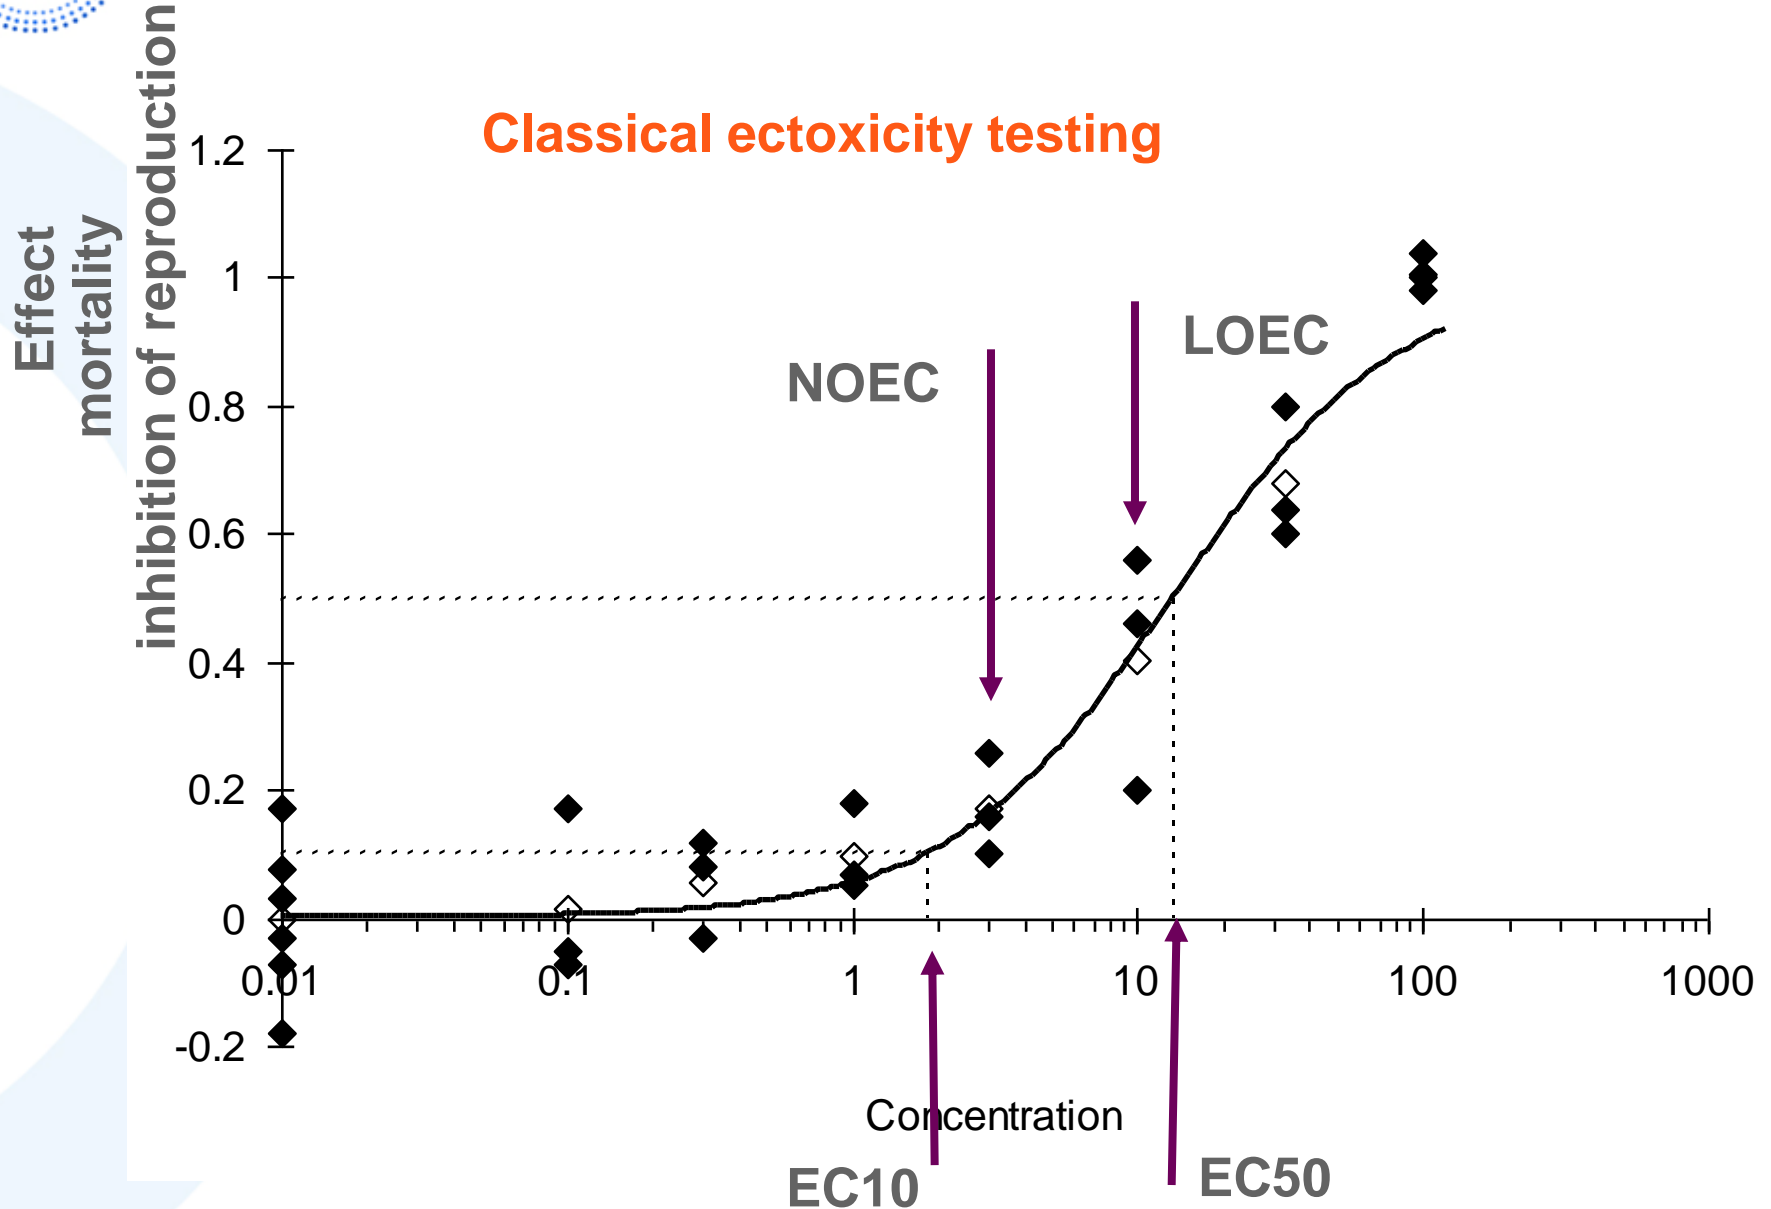

Introduction

Everything is a poison. It is the dose that makes things non toxic.

Paracelsus (1520?)

From exposure to effect

What type of effects can be measured?

Every compound can cause death (depending on the dose c.f. Paracelsus)

But does every compound induce behavioural changes?

Aim: quantify the sensitivity of the toximeter

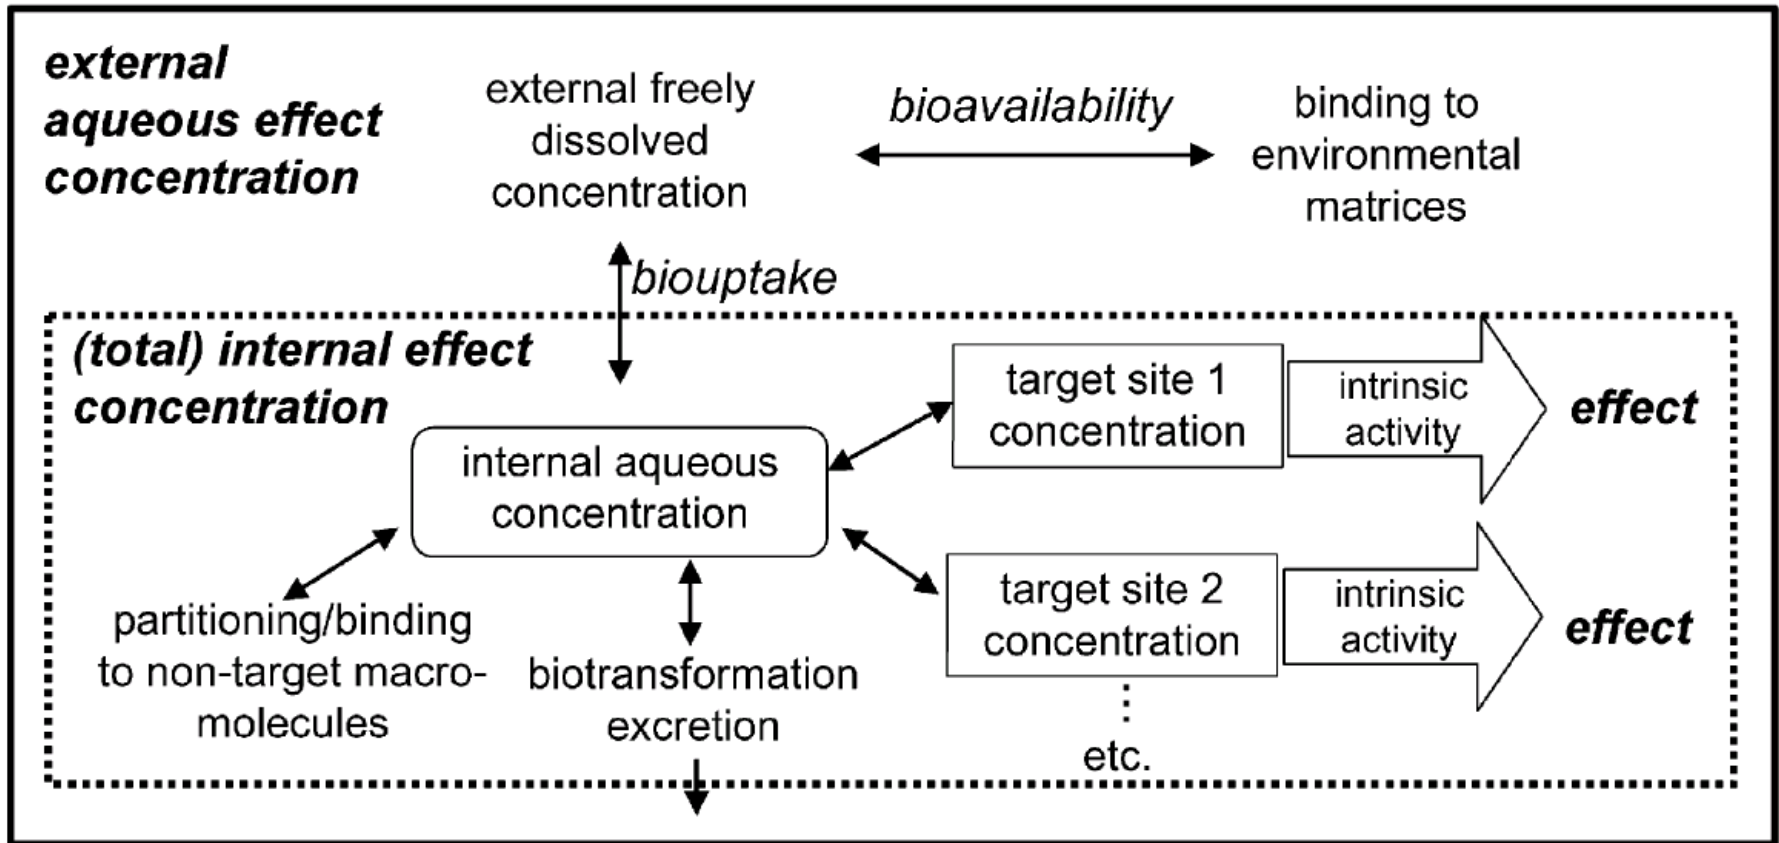

- understand how sensitivity can be generalised
- analyse and potentially predict sensitivity of toximeter towards specific compounds
 - alarm threshold \ll EC50
 - alarm threshold \approx EC50

Sensitivity is not a universal feature -

anecdotal evidence → mechanistic understanding

From exposure to effect

total or nominal concentration

Introduction – Terminologie

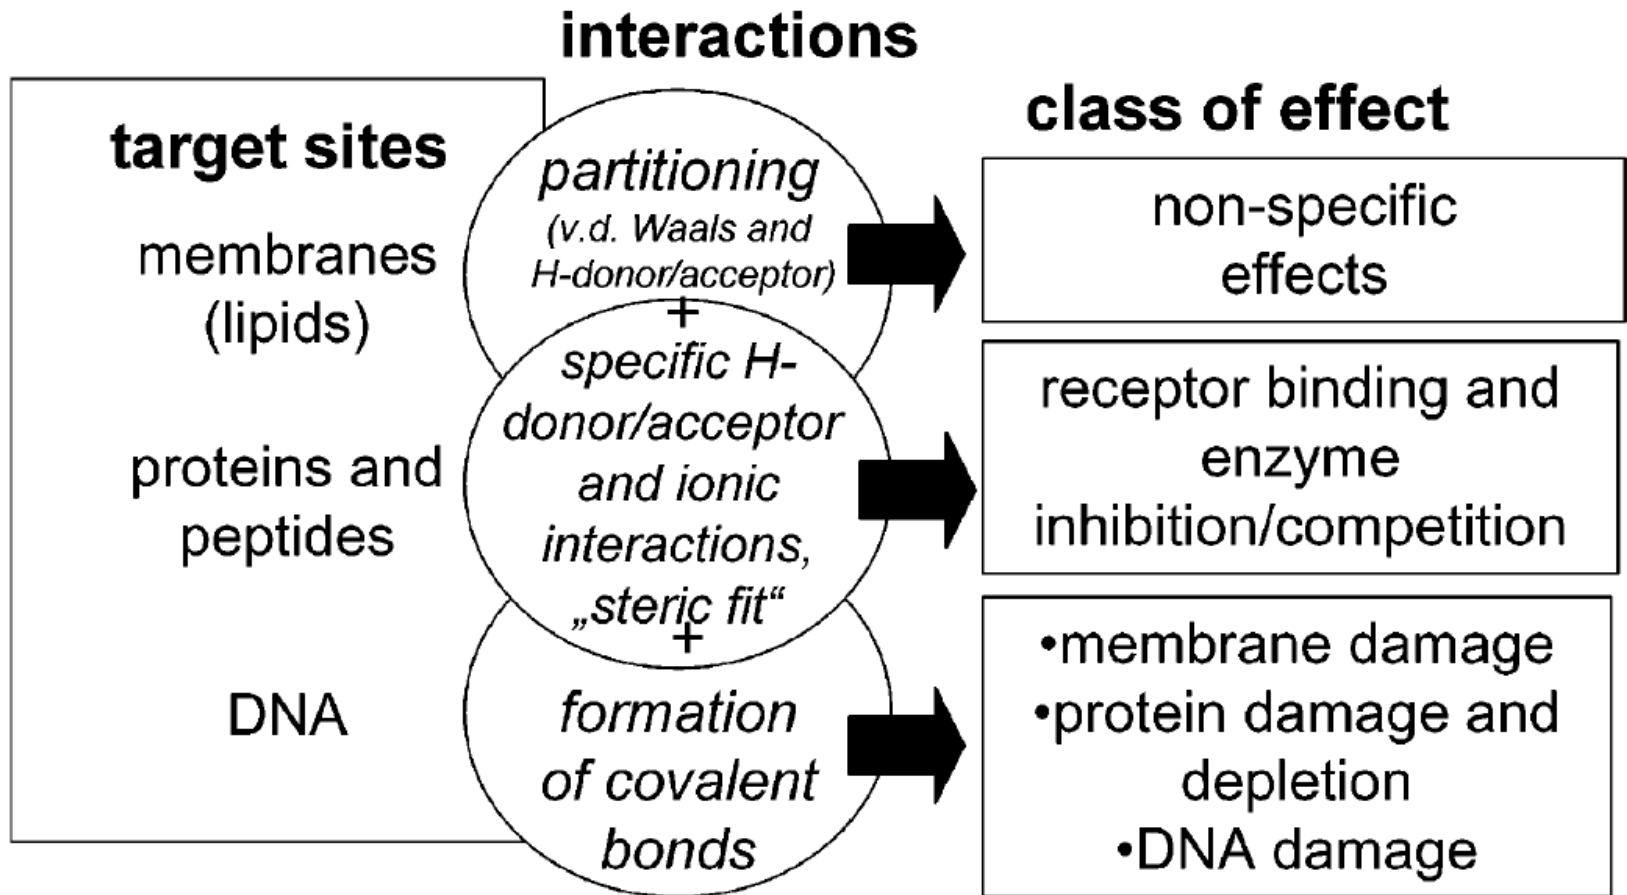

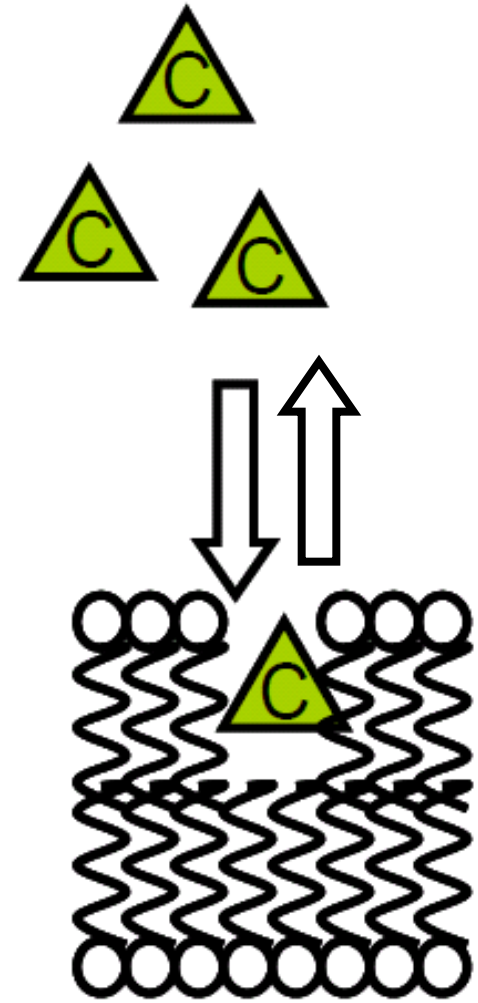

FIGURE 2. Rationale behind the classification of chemicals according to mechanism: target sites and type of interaction.

Non-Specific Effects - Baseline Toxicity

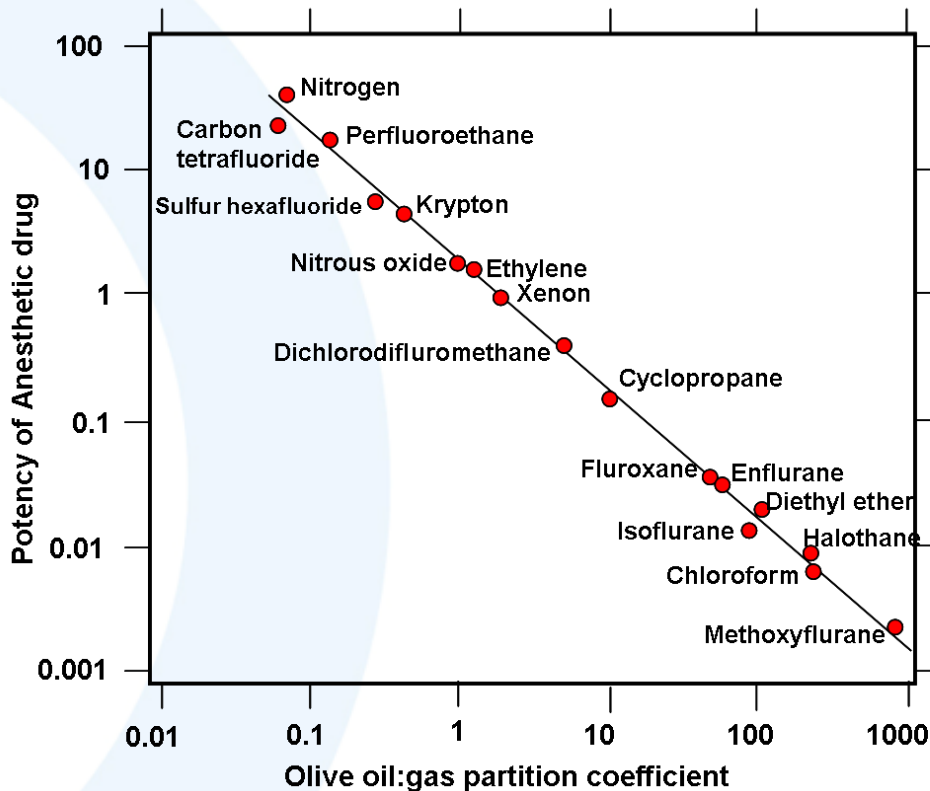

Mode of action:

- partitioning of compounds in biological membranes
- non-specific perturbation of integrity and function of membranes

Narcosis in Pharmacology

The Meyer-Overton correlation for anesthetics

Narcosis theory, postulated by Meyer (1899) and Overton (1902) based on the observation:

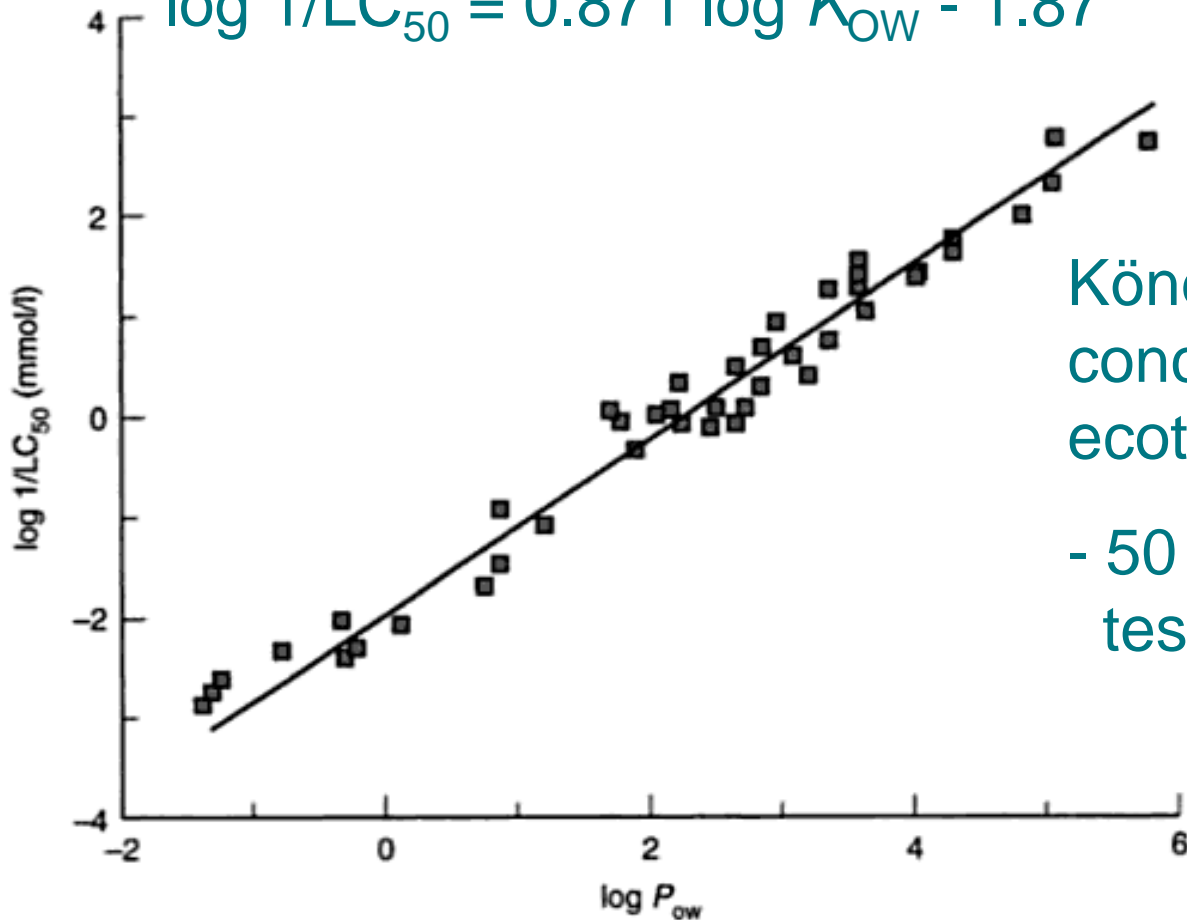

« The aesthetic potential of a compound is proportional to its lipophilicity. »

Meyer (1899). "Zur Theorie der Alkoholnarkose". *Arch. Exp. Pathol. Pharmacol.* **42**

Overton (1901). "Studien über die Narkose zugleich ein Beitrag zur allgemeinen Pharmakologie". *Gustav Fischer, Jena*

Narcosis in Ecotoxicology

$$\log 1/LC_{50} = 0.871 \log K_{OW} - 1.87$$

Könemann adopted the concept of narcosis to ecotoxicology

- 50 industrial compounds tested for fish toxicity

Figure I.2 Representation of the Könemann equation: the relationship between the toxicity to fish ($\log 1/LC_{50}$ in mmol/l) of 50 industrial pollutants and their 1-octanol/water partition coefficient ($\log P_{ow}$). The regression line is given by $\log 1/LC_{50} = 0.871 \log P_{ow} - 1.87$ (Könemann, 1981b).

Könemann, H. (1981), "Quantitative Structure-Activity Relationships in fish toxicity studies. Part 1: relationship for 50 industrial pollutants", *Toxicology*, 19, 209-221.

Baseline Toxicity

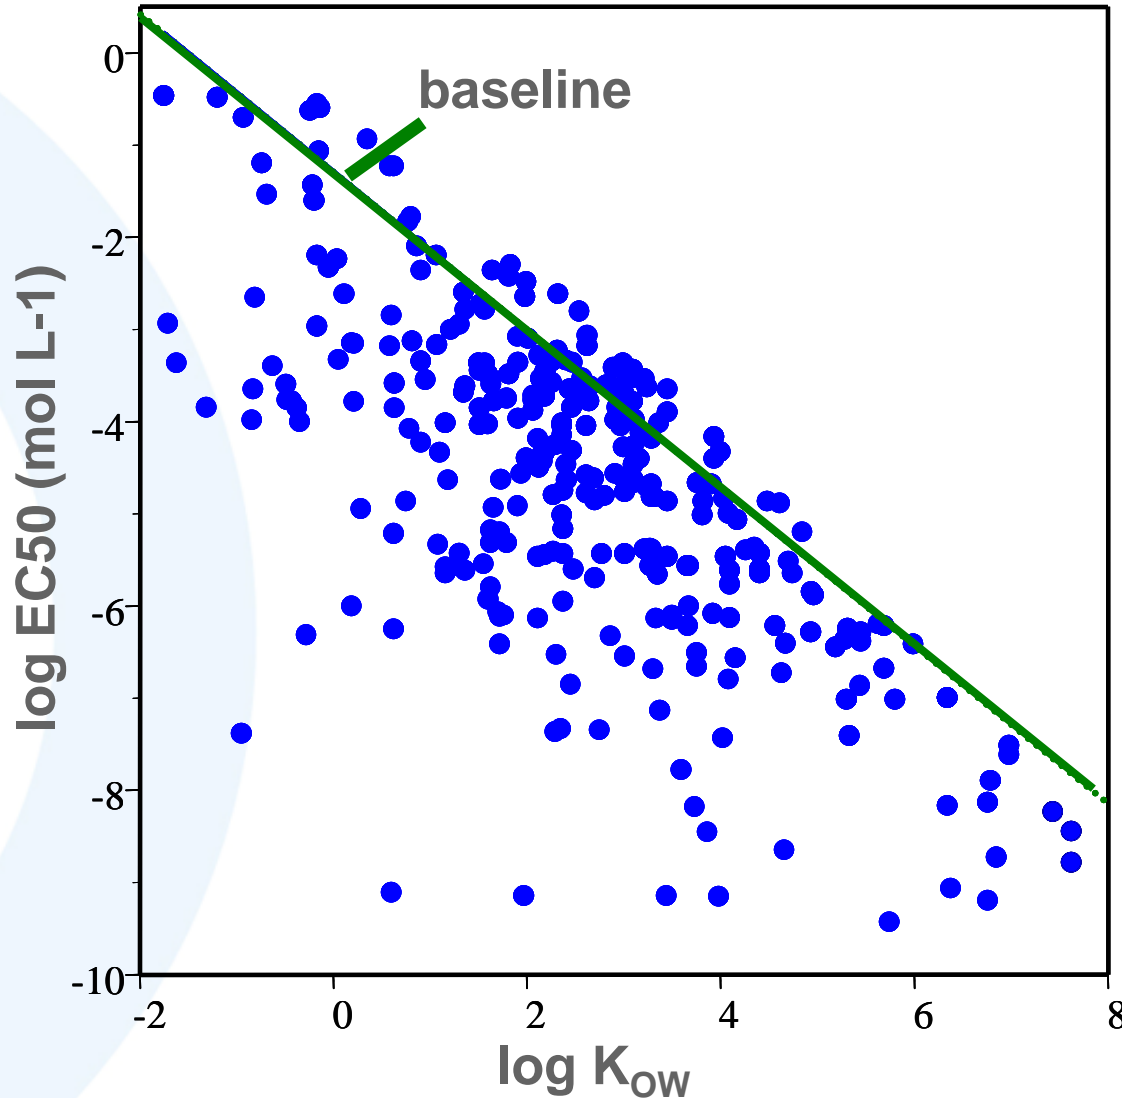

$$\log EC_{50} = a * \log K_{OW} + b$$

Taxa	Dauer	Endpunkt	a	b

Same type of relationship can be observed for all species

Baseline Toxicity

Algal toxicity as a function of $\log K_{ow}$ (EC₅₀ of 300 substances)

→ **Baseline toxicity is the minimal toxicity**

Baseline Toxicity - Conclusion

- universal effect
 - all species
 - all organic compounds
- reversible effect
- ➔ minimal toxicity (no compounds can be less toxic than acting via partitioning)

ca. 70% of all compounds exert toxicity in the narcosis range (observed toxicity within a factor of 100 of prediction based on lipophilicity)

Reactive and Specific Modes of Action

- reactive and specific compounds are more toxic than predicted from their lipophilicity
- reactive and specific compounds interact directly with target sites
 - formation of chemical bonds
 - receptor affinity
- ➔ Their toxicity depends not only on target site concentration but also on the intrinsic potential to react or to bind.

Reactivity

- reactive molecules (i.g. electrophiles) can form covalent bonds with biomolecules
 - alkylation and oxydation of
 - membranes
 - proteines
 - glutathion
 - DNA
- non-reversibles effects

Specific Modes of Action - Inhibition or Competition

- compounds with similar structure to a biomolecule:
 - blocking or competition to molecular receptor.

- Acetylcholinesterase
- Estrogene receptor
- Ah-receptor

→ perturbation signal transmission

→ Activity typically limited to a group of species

 Natural Molecule

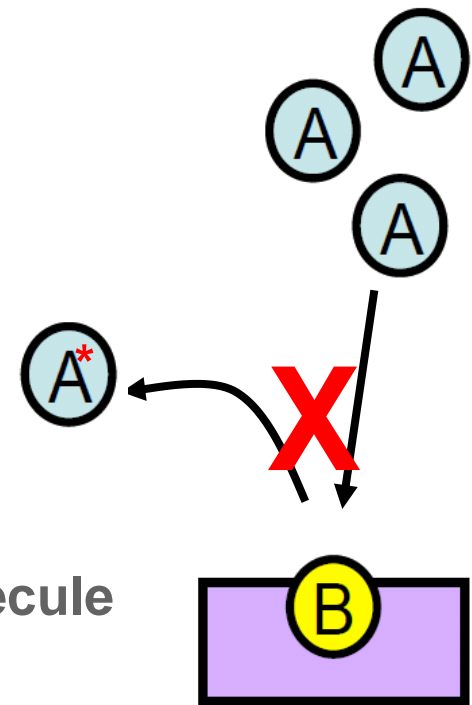

Specific Modes of Action - Inhibition or Competition

- compounds with similar structure to a biomolecule:
 - blocking or competition to molecular receptor.

- Acetylcholinesterase
- Estrogene receptor
- Ah-receptor

→ perturbation signal transmission

→ Activity typically limited to a group of species

Specific Target Sites

A RECEPTORS

(eg beta blockers, 17 α -ethinylestradiol)

B ION CHANNELS

(eg local anaesthetics, cypermethrin)

● Agonist/normal substrate

● Abnormal product

● Antagonist/inhibitor

● Pro-drug

C ENZYMES

(eg aspirin, ketoconazole)

D TRANSPORTERS

(eg fluoxetine, omeprazole)

Note – a few drugs target DNA rather than proteins (eg mitomycin C).

Interference with these sites are specially targeted for development of pesticides (or pharmaceutiques)

Specific Modes of Action of Insecticides

- Neurotoxics
Perturbation of neurotransmission
- Endocrine disruptors
Interaction with mechanisms regulating growth and development
- Action on cellular respiration

Neurotoxics

Perturbation of neurotransmission

- Inhibition of Acetylcholinesterase (AChE)
- Agonists of the nicotinic cholinergic receptor (nAChR)
- Sodium channel modulateur
- Muscular ryanodine receptor modulators

Neurotoxic: Inhibition of AChE

Neurotoxic: Inhibition of AChE

Agonists of the Nicotinic Cholinergic Receptor (nAChR)

Interaction with Mechanisms Influencing Growth and Development

Agonistes of ecdysone

L'ecdysone : - steroid hormone
- interferes with moulting of arthropodes

agonist of ecdysone : - imitation of hormone
- provokes premature moulting

Summary

Modes of action may contribute to understanding of detectability of compounds in the toximeter

- several modes of action are potentially relevant for behavioural changes
 - neurotoxins
 - endocrine disruptors
- compounds with other modes of action may only be detectable at EC50 concentration

Einführung

Für die Vorhersage eines Mischungseffektes muss man die Konzentrations/Dosis-Wirkungsbeziehungen aller Stoffe der Mischung kennen.

Für die Beurteilung einer potentiellen Interaktion zwischen den Stoffen (Synergie oder Antagonismus) braucht man eine Vorstellung (Konzept oder Modell) für Mischungseffekt ohne Interaktion:

Formulierung einer **Nullhypothese**.

aber:

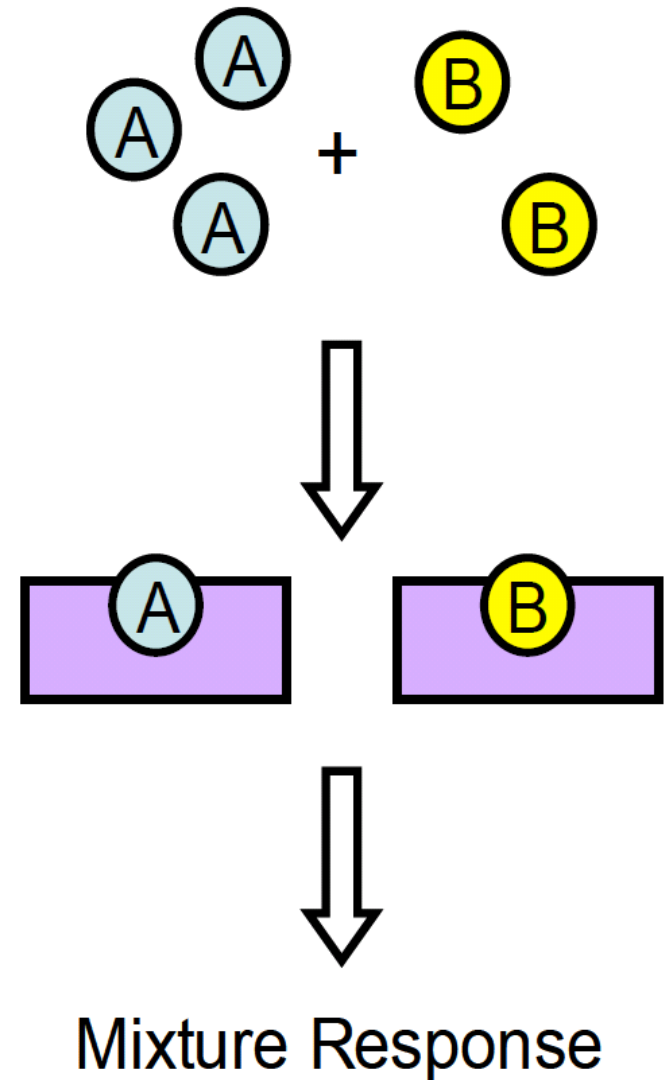

Was ist ein vernünftige Hypothese für einen Mischungseffekt?

Vorhersagemodelle

Concentration Addition (CA)

Hypothese:

- Ähnliche Wirkmechanismen
 - identischer Wirkort
 - (eventuell unterschiedliche Wirksamkeit)
- Eine Substanz kann als Verdünnung der anderen betrachtet werden.

Vorhersagemodelle

Concentration Addition (CA)

Universelle Formel

$$\sum_{i=1}^n \frac{c_i}{ECX_i} = 1$$

n = Anzahl Substanzen
c_i = Konz von Substanz i
EC_x = Effektkonz. X%
X = Effektlevel in %

Formel für binäre Mischungen

$$\frac{c_1}{ECX_1} + \frac{c_2}{ECX_2} = 1$$

Vorhersagemodelle

Independent Action (IA) Response Addition (RA)

Hypothese:

- Unähnliche Wirkmechanismen
- Unterschiedliche Wirkorte
- ➔ Der Effekt einer Substanz ist völlig unabhängig von der anderen (auch im statistischen Sinne).

Vorhersagemodelle

Independent Action (IA) Response Addition (RA)

Universelle
Formel

$$E(c_{mix}) = 1 - \prod_{i=1}^n [1 - E(c_i)]$$

Formel für
binäre Mischungen

$$E(c_{mix}) = E(c_1) + E(c_2) - E(c_1) \cdot E(c_2)$$

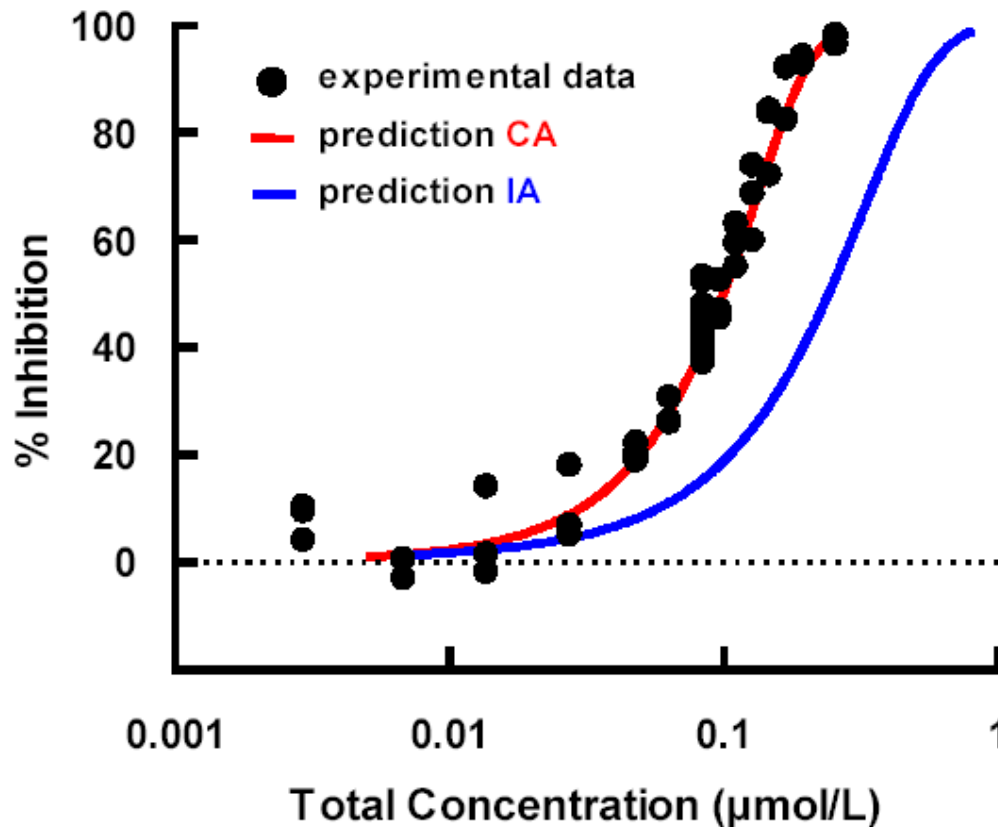

n = Anzahl von Substanzen

c_i = Konz der Substanz i

$E(c_i)$ = Effekt der Konz c_i von Substanz i

Referenzfälle

Common specific mechanism of action:
18 s-triazines

Das CA-Modell sagt die Toxizität von Mischungen ähnlich wirkende Stoffe korrekt vorher in verschiedenen Testsystemen (Algen und Bakterien) und in verschiedenen Mischungsverhältnissen (EC50 et EC01)

Altenburger R, Backhaus T, Boedeker W, Faust M, Scholze M, Grimme LH. 2000. Predictability of the toxicity of multiple chemical mixtures to *Vibrio fischeri*: Mixtures composed of similarly acting chemicals. *Environ Toxicol Chem* 19:2341–2347.

Referenzfälle

Different specific mechanisms of action:
16 pesticides and antibiotics

Das IA-Modell sagt die Toxizität von Mischungen unähnlich wirkender Stoffe korrekt vorher in verschiedenen Testsystemen (Algen und Bakterien) und in verschiedenen Mischungsverhältnissen (EC50 et EC01)

Backhaus T, Altenburger R, Boedeker W, Faust M, Scholze M, Grimme LH. 2000. Predictability of the toxicity of a multiple mixture of dissimilarly acting chemicals to *Vibrio fischeri*. *Environ Toxicol Chem* 19:2348–2356.

Implikationen der Modelle

CA

- ⊙ Jeder Stoff der Mischung trägt zum Kombinationseffekt bei (selbst wenn er einzeln keinen Effekt hervorruft (low dose)
 - ⊙ Für Umweltmischungen können sich daraus Problemen ergeben (Organismen können hunderten oder tausenden Stoffen gleichzeitig exponiert sein)
- ⊙ Berechnung auf Basis von EC50-Werten möglich (nicht aus NOEC, LOEC, etc.) für das gleiche Effektniveau (z.B. Toxic Units).

IA

- ⊙ Wenn eine Substanz allein keinen Effekt erzeugt, trägt sie auch nicht zum Kombinationseffekt bei.
- ⊙ Für die Berechnungen müssen kleine Effekte der Einzelstoffe quantifiziert werden.
 - ⊙ Das ist in der Regel schwierig.
 - ⊙ Entsprechende Informationen sind nicht verfügbar.
- ⊙ Berechnung aus EC50, NOEC oder LOEC ist nicht möglich.

Conclusion

Mixture toxicity is reasonably well predictable

Synergistic effects are rather rare in environmental samples

Typically toxicity of environmental samples is driven by few main contributors to toxicity (despite hundreds of compounds present at low dose).

All evidence from classic toxicity tests

Aim:

Is mixture toxicity predictable when using non-classical endpoints (behaviour)?

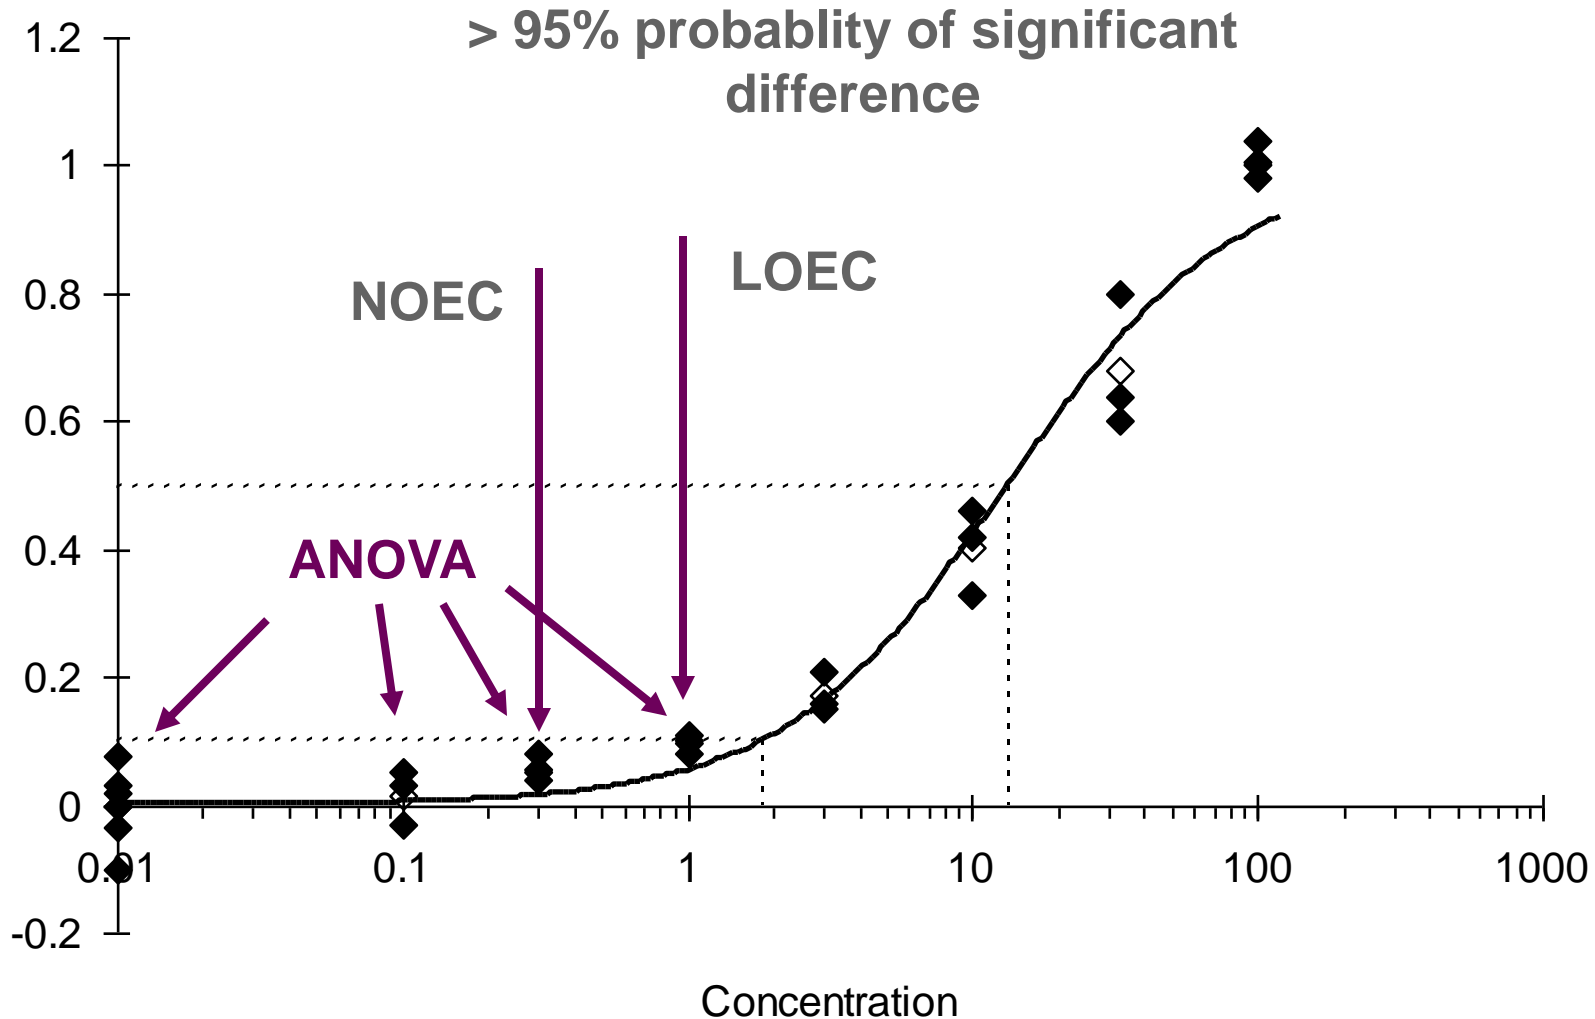

Does the presence of multiple low-dose compound mixtures increase the sensitivity of the toximeter?

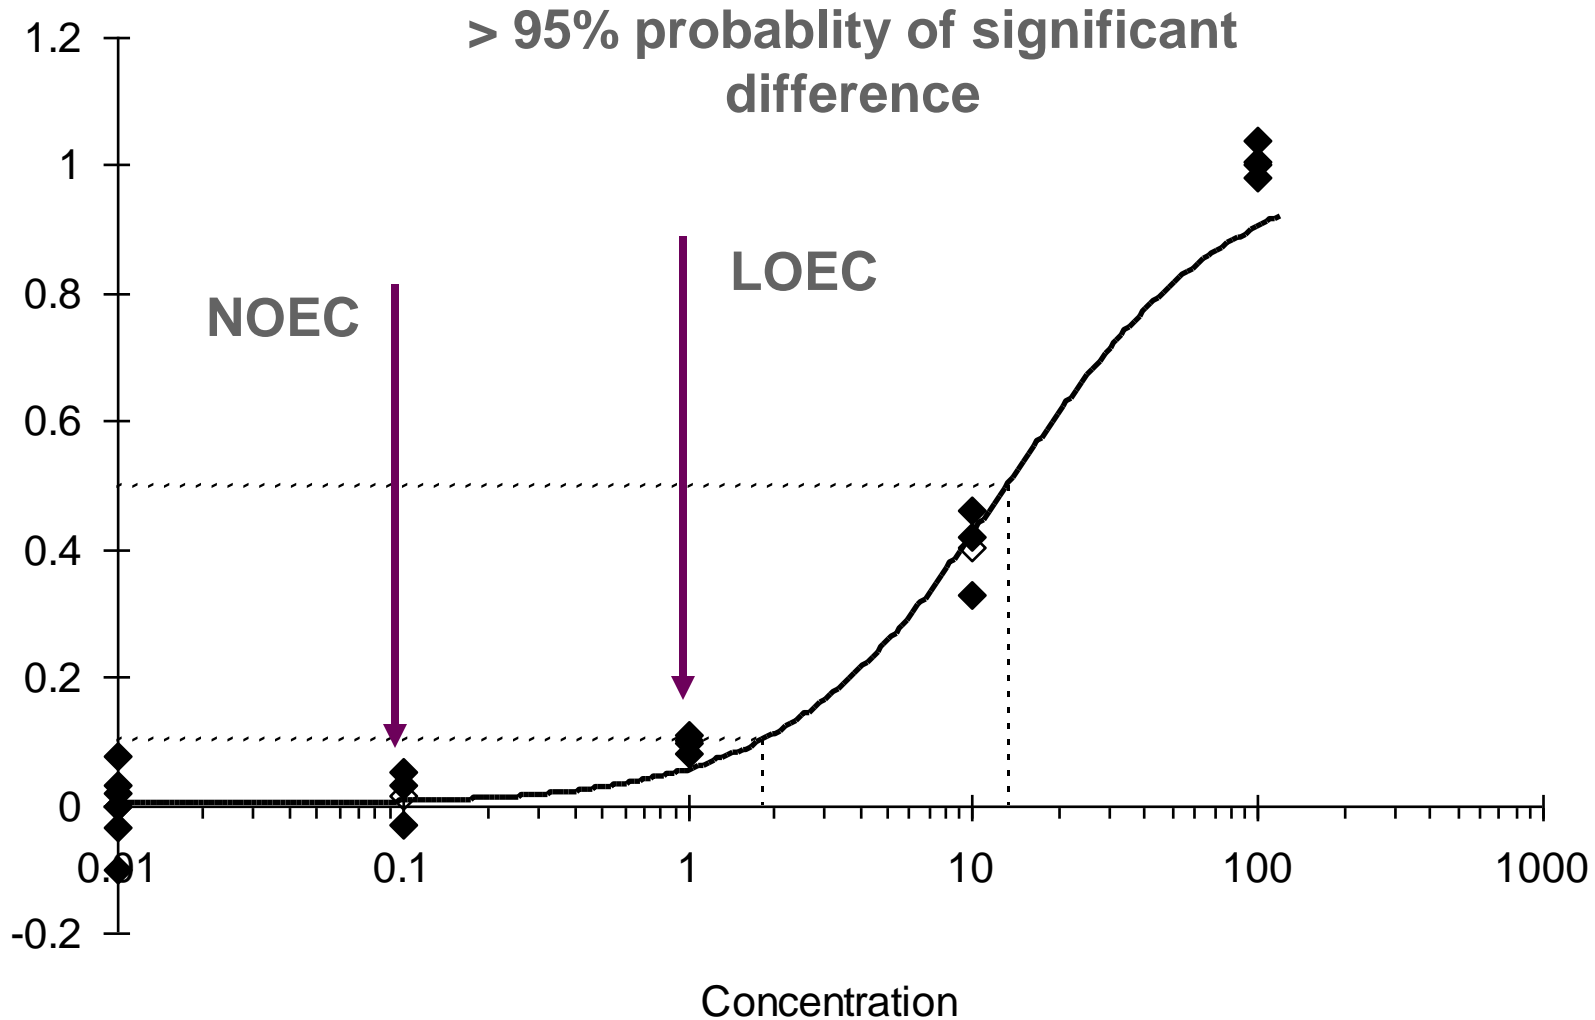

Thank you for your attention
